

NANA WALLET

A consumer financial product with a **dual-user model**

Independence for the person using it. Protection for the person who cares for them.

The thesis

Nana is not "a wallet for the elderly". That framing hides the mechanism that makes it work.

THE DEFINITION

Nana is a free agentic financial account with a dual-user model: independence for the person using it, and protection for the person who cares for them.

Three roles have to be told apart, because confusing them is what makes every other question unanswerable.

FIGURE 1 · WHO DOES WHAT

THE CENTRAL INSIGHT

The responsible absorbs the complexity once, so the user gets simplicity every day.

AND THE RULE THAT KEEPS IT A PRODUCT

The responsible must not approve every payment. The moment they do, independence was not returned, it was transferred. Intervention happens by exception only. This single rule is what separates Nana from parental controls, and it should survive every future product decision.

Onboarding: the responsible does the ugly part

Setup is a one-time cost, paid by the person equipped to pay it. The end user should never see this screen.

FIGURE 2 · SETUP FLOW, PERFORMED ENTIRELY BY THE RESPONSIBLE

- 1 **Downloads Nana.** Driven by an ad or by content aimed at 35 to 60 year olds, not at seniors.
- 2 **Creates a family account** and invites the parent.
- 3 **KYC and wallet creation.** The heaviest, most abandonment-prone step, and it happens here, not with the senior.
- 4 **Configures the family graph:** recipients by name (Tomi, grandson · Marcos, son), service providers, daily limit, trusted recipients, alert contacts.
- 5 **Funds the account.** ARS through a partner, settled into stablecoin.

Setup complete
Everything above happens once, and never again

"Hey Nana"
The end user's first and only interface

WHY THIS ORDERING MATTERS COMMERCIALY

KYC, funding and configuration are where consumer fintech loses most of its funnel. Moving all three onto a motivated, capable buyer changes the conversion math of the entire product, before a single feature is built.

Daily use: the wallet disappears

After setup, Nana should stop looking like a financial app at all.

FIGURE 3 · ONE PAYMENT, END TO END

Protection: the second product

The same account behaves differently depending on what is being asked of it.

FIGURE 4 · TWO PAYMENTS, TWO PATHS

THE LOAD-BEARING RULE, RESTATED

Normal activity: user → Nana. Unusual activity only: user → Nana → responsible.

WHERE THE LIABILITY SITS, AND HOW IT IS CONTAINED

Any product that says it detects scams carries exposure when it misses one. That exposure is smaller when protection is a free, universal property of the account rather than a paid promise. Charging for safety converts a best-effort feature into a purchased guarantee, which is a materially worse legal position. Keeping the safety floor free is the containment strategy, not a giveaway.

Three monetization hypotheses

Not one business model. Three bets, to be validated in sequence rather than launched together.

FIGURE 5 · REVENUE ARCHITECTURE

Layer 1 · The wallet is free, activity is monetized

Nana is downloaded and used for free. Usage generates volume through a financial partner, and Nana takes a share of the fee or spread rather than charging the senior a visible percentage.

THE NUMBER THIS LAYER HAS TO SURVIVE

Older adults are, by definition, low-volume users. Ten payments of \$20,000 ARS per month is roughly USD 150 of monthly volume. At a 1% spread split evenly with the partner, that is well under one dollar per user per month. **Layer 1 is presented first but may be the weakest of the three.** Either the volume assumption is wrong, or the sequencing is, and knowing which one is a research question, not an opinion.

Layer 2 · Nana Family, sold on capability

THE LINE THAT MUST NOT BE CROSSED

Safety is never the upsell. Every Nana account, paid or not, gets the confirmation step, the limits and the anomaly detection. The subscription sells reach, control and convenience, never protection itself.

Charging for protection would mean the free product knowingly leaves someone exposed. That is bad to sell, bad to defend, and it manufactures the exact liability the company should be avoiding. The paid tier has to earn its price on capability instead.

NANA, FREE · SAFETY INCLUDED	NANA FAMILY · CAPABILITY
Wallet and voice agent Send, receive, balance, bill payment Confirmation step on every movement Daily limit and trusted recipients Anomaly detection and hold One alert contact	Everything free, plus: Several responsible contacts, with roles Several seniors on one family account Family dashboard and exportable reports Recurring payments and bill autopay Fine-grained policies, per recipient and per category Full history and statements Priority human support

The pitch is not **pay to keep your mother safe**. It is closer to **you are looking after two parents, from another city, with your sibling. Here is the account that handles that**. A caregiving household with real coordination needs is a different customer from one adult child with one parent, and only the first one has a reason to pay.

WHAT STILL HAS TO BE PROVEN

Willingness to pay is asserted, not measured. The honest test is narrow: does a household with more than one caregiver, or more than one dependent, hit a wall in the free tier that they want removed? If the free tier is enough for almost everyone, this layer does not exist and the answer is layer 1 or layer 3.

Layer 3 · B2B2C, the largest and least certain

Rather than acquiring every older adult individually, Nana becomes a layer an institution offers: **Nana Mode, powered by [bank]**. The bank already has users, KYC, ARS accounts, cards, QR and compliance. Nana contributes the voice agent, the accessibility, the family relationships, the protection policies and the agentic execution. Priced per active user, as an enterprise licence, or as revenue share.

THE ASSUMPTION UNDERNEATH

That banks want this. They carry accessibility obligations but modest commercial incentive. This is the most speculative of the three and should be labelled that way in any conversation.

Sequence, and go to market

FIGURE 6 · WHAT GETS VALIDATED BEFORE WHAT

Go to market: you do not acquire the senior

FIGURE 7 · ACQUISITION PATH

THE POSITIONING THAT FOLLOWS FROM IT

Not "are you 78? download our crypto wallet". Instead: give your parents financial independence without giving up your peace of mind.

The loop worth testing

The responsible downloads Nana and invites a parent. The parent uses it and adds family recipients. Those relatives see Nana working inside their own family. Some of them become the responsible in another household.

Whether this behaves as a real growth loop is unknown. It is cheap to instrument and worth measuring early.

The model on one page

QUESTION	ANSWER
Who uses it?	The older adult, or a person with limited mobility.
Who sets it up?	The son, daughter or responsible family member.
Who may pay?	The responsible, or the financial partner. Not the end user.
Who distributes?	Nana directly at first. Banks and fintechs eventually.
How does it make money?	Financial revenue share, then Nana Family premium, then B2B2C licensing.

Confidence, stated honestly

CLAIM	CONFIDENCE	WHY
Dual-user architecture	High	Falls out of how the product is actually used and set up.
Go to market through the responsible	High	Follows directly from who makes the purchase decision.
Exception-only intervention	High	Required by the product's own promise. Break it and independence is gone.
Nana Family subscription	Medium	Sold on capability, not on safety. Depends on whether multi-caregiver households hit a real wall in the free tier.
Transaction revenue as layer 1	Low	Per-user volume for this segment is small. The arithmetic has to be run.
B2B2C licensing	Low	Assumes institutional appetite that has not been tested.

MISSING FROM THIS DOCUMENT, AND NEEDED BEFORE ANY INVESTOR CONVERSATION

Regulation. ARS on and off ramp, stablecoin custody, third-party funds, and a vulnerable-adult user base. Argentina's PSAV regime and the compliance path are absent here, and they shape which of the three layers is even legal to run alone.

WHAT TO SAY IN THE ROOM

The user architecture and the go to market are defined. The revenue model is three hypotheses, not a conclusion. Validate who adopts, who uses and who pays, and the revenue question stops being speculative.
