

NANA WALLET

Say what you want. **Confirm what matters.**

An agentic wallet that gives older adults their financial independence back, without asking their family to give up peace of mind.

THE PROBLEM

We protect the people we love by **taking things away from them.**

I watched it happen with both of my grandmothers. Someone else paid the bills. Someone else managed the money. Someone else decided.

WHY FAMILIES DO IT

One of my grandmothers was actually scammed. For her generation cash was tangible. That made her readable to people who knew exactly how to exploit that trust.

AND WHAT IT COSTS

She was safer. She was also becoming less independent. The family instinct to take control is not irrational: it is the only tool anyone has ever given them.

WHY NOW

We are living longer while financial life moves *entirely* onto screens.

- One of the fastest growing segments of the population is served by interfaces designed for nobody in it.
- In Argentina, what an older adult with savings most wants is to hold dollars. **Stablecoin rails are built for exactly that.**
- The caregiving relationship is universal and recurring, and has no **financial** software built for it.

THE REFRAME

**Fintech competes on removing friction.
5 clicks become 3. 3 become 2.**

We asked a different question.

Which interaction actually deserves to exist?

THE PRODUCT

The interface becomes a conversation.

The agent does the work. The user makes the one decision that carries consequence.

THE INSIGHT

Nana has **two users**, not one.

THE OLDER ADULT

Uses it

Speaks. Confirms. Pays their own bills again. Nobody takes over.

THE ADULT CHILD

Buys and configures it

Stops running someone else's money. Told only when it matters.

The responsible absorbs the complexity once,
so the user gets simplicity every day.

**The family must not approve
every payment.**

**The moment they do, independence
was not returned.
It was transferred.**

HOW PROTECTION WORKS

Normal activity: user to Nana.

Unusual activity only: user to Nana to family.

ORDINARY

"Send ARS 15,000 to Sofi"

Known recipient. Usual amount. Normal behaviour.

Confirms and goes. The family is never involved.

UNUSUAL

"Send ARS 900,000 to this account"

New recipient. Unusual amount. Over limit.

Held. The family is alerted, and decides.

Safety is never the upsell. The confirmation step, the spending limit and the recipient allowlist are built and running. Anomaly detection and the family alert are designed and next. Every account gets both, free, including one responsible who can approve and block.

IT IS NOT A MOCKUP

Nana already executes real transactions.

7

agentic transfers, end to end

Voice, agent, prepared transaction, human confirmation, signature, settlement. The full path working on Ethereum Sepolia, through the Tether WDK.

2nd place Tether WDK track

Aleph Hackathon 2026. Built in one weekend, against 650 hackers and 150 projects.

What is actually built

Agent, confirmation step, spending limit, recipient allowlist and onchain receipt verification. The safety floor is code, not a diagram.

Testnet, with test tokens. Recipients were wallets we control, which is how the agentic path was exercised safely before touching anyone's money.

Nana is distribution of digital dollars to the people who want them most and reach them least.

- The user wants dollars, not crypto. Nana removes the entire crypto surface: no seed phrase, no address, no network to choose.
- Because the user never picks the chain, **we do**. Settlement becomes a decision we own, not a preference that walks away tomorrow.
- A 78 year old cannot be asked to hold a gas token. Gas abstraction is a precondition here, not a nicety.

WE HAVE BUILT ON ARC TWICE. NOT WITH NANA, YET.

FUD on Arc · agent-driven P2P USDC markets, settled on Arc.

122 Arc Testnet micropayments · zero failed, chain 5042002.

Hello, Physical World · that build, written up for the Arc community.

THE CIRCLE STACK WE WANT

USDC · Arc · CCTP · Circle Mint · Programmable Wallets and Paymaster for gasless execution.

The wallet layer is swappable: we placed 2nd in the Tether WDK track at Aleph and built there.

BUSINESS MODEL

Three hypotheses, validated in sequence. Not three launches at once.

LAYER 1

Financial activity

Revenue share on the rails. The real margin is dollarization, float on balances and recurring bill payment, not transfer spread.

LAYER 2

Nana Family

Subscription, priced per protected person. Never per family member: more eyes on the account is the safest configuration.

LAYER 3

B2B2C licensing

Banks have accounts. They do not have families. The family graph is the licensable asset.

The wallet is free, and so is protection. We are explicit that these are hypotheses, not conclusions.

People over 75.

- **TAM**
Everyone the product could serve
- **SAM**
Where we can operate and charge
- **SOM**
What we underwrite in three years

Hand motor impairment, 18+.

- **TAM**
Everyone the product could serve
- **SAM**
Where we can operate and charge
- **SOM**
What we underwrite in three years

Two ways into the same product.

People over 75

Age removes the interface, not the will

Hand motor impairment, 18+

The hands fail before the judgement does

The two populations overlap, so we do not add them. Voice replaces the interface in both cases, which is why one product serves both. Argentina in three years is the number we are actually underwriting.

You do not acquire the senior. You acquire the daughter.

- The purchase decision is made by someone 35 to 60, with a smartphone, income, and a parent they worry about.
- Configuration and funding move onto the person equipped to complete them. The account stays in the senior's name: the child assists the process, never replaces the owner.

**Give your parents financial independence
without giving up your peace of mind.**

WHERE WE ARE

Working product on testnet. Two experiments running now.

EXPERIMENT 1 · 3 WEEKS

Does complexity drive payment?

20 interviews with adult children aged 35 to 60, counting how many have more than one dependent parent. A priced fake door tests willingness to pay before a single rail is built.

EXPERIMENT 2 · 4 WEEKS

Can an 80 year old use it?

Moderated sessions with adults over 70, measuring completion without help. For a product whose thesis is accessibility, this is the number that matters most.

Shipped: agent, confirmation flow, family graph, protection policies, real onchain settlement, mobile builds. Open: the custody and licensing path, which we are working through with local partners.

THE TEAM

**The people who built this in a weekend
and did not stop after it.**
